Abstract

Disclosed is a device (30) for manually controlling the position of switching means which have two extreme positions A and C and an intermediate position B. Said 5 device comprises a crank (5) and a crankpin (6). The invention is characterized by the fact that the device comprises a translationally movable sliding member (1) that has a neutral position and is provided with quideways (20, 21), within which the crankpin (6) 10 displaced. Said guideways allow the crankpin to be quided towards three areas of the sliding member, in the position thereof is stable and correspond to the three positions of the switching means, when the sliding member is moved towards the 15 neutral position. The inventive device has the advantage of being simple while allowing a change in the state of the motor which operates the closing element, darkening element, or sun-shading element, or sun-shading element to be controlled by means of a 20 single movement of a rod (14).
